

Coupling Metrics

Instability - Overview

Afferent Coupling (C_a)

Definition → "dependents"
Modules/packages that depend on given module/package

Analogy → "Creditors"
They rely on your stability

Impact → $\uparrow C_a = \uparrow \text{Stability}$

Higher C_a → Module is *more* "stable" and harder to change (many rely on it).

Instability (I)

$$I = C_e / (C_e + C_a)$$

$0.0 \leq I < 0.25$ **$I \rightarrow$ Stable**

Many dependents, few dependencies.
Change with care.

$0.25 \leq I < 0.5$ **$I \rightarrow$ Mostly Stable**

Goldilocks zone. Normal dev pace.

$0.5 \leq I < 0.75$ **$I \rightarrow$ Borderline**

Caution zone. Monitor closely and prepare for refactoring.

$0.75 \leq I \leq 1.0$ **$I \rightarrow$ Volatile**

Few dependents, many dependencies.
Refactor freely.

Efferent Coupling (C_e)

Definition → "dependencies"
Modules imported by given module

Analogy → "Debtors"
Their problems become yours

Impact → $\uparrow C_e = \uparrow \text{Instability}$

Higher C_e → Given Module is *less* stable, and more prone to breakage due to changes in other modules.

Afferent (C_a) & Efferent (C_e) Coupling and Instability (I) Overview
by: Steven Miers

Figure 1: Overview -- Calculating coupling and instability metrics

$$I = C_e / (C_e + C_a)$$

Coupling Metrics

Instability (I) Index

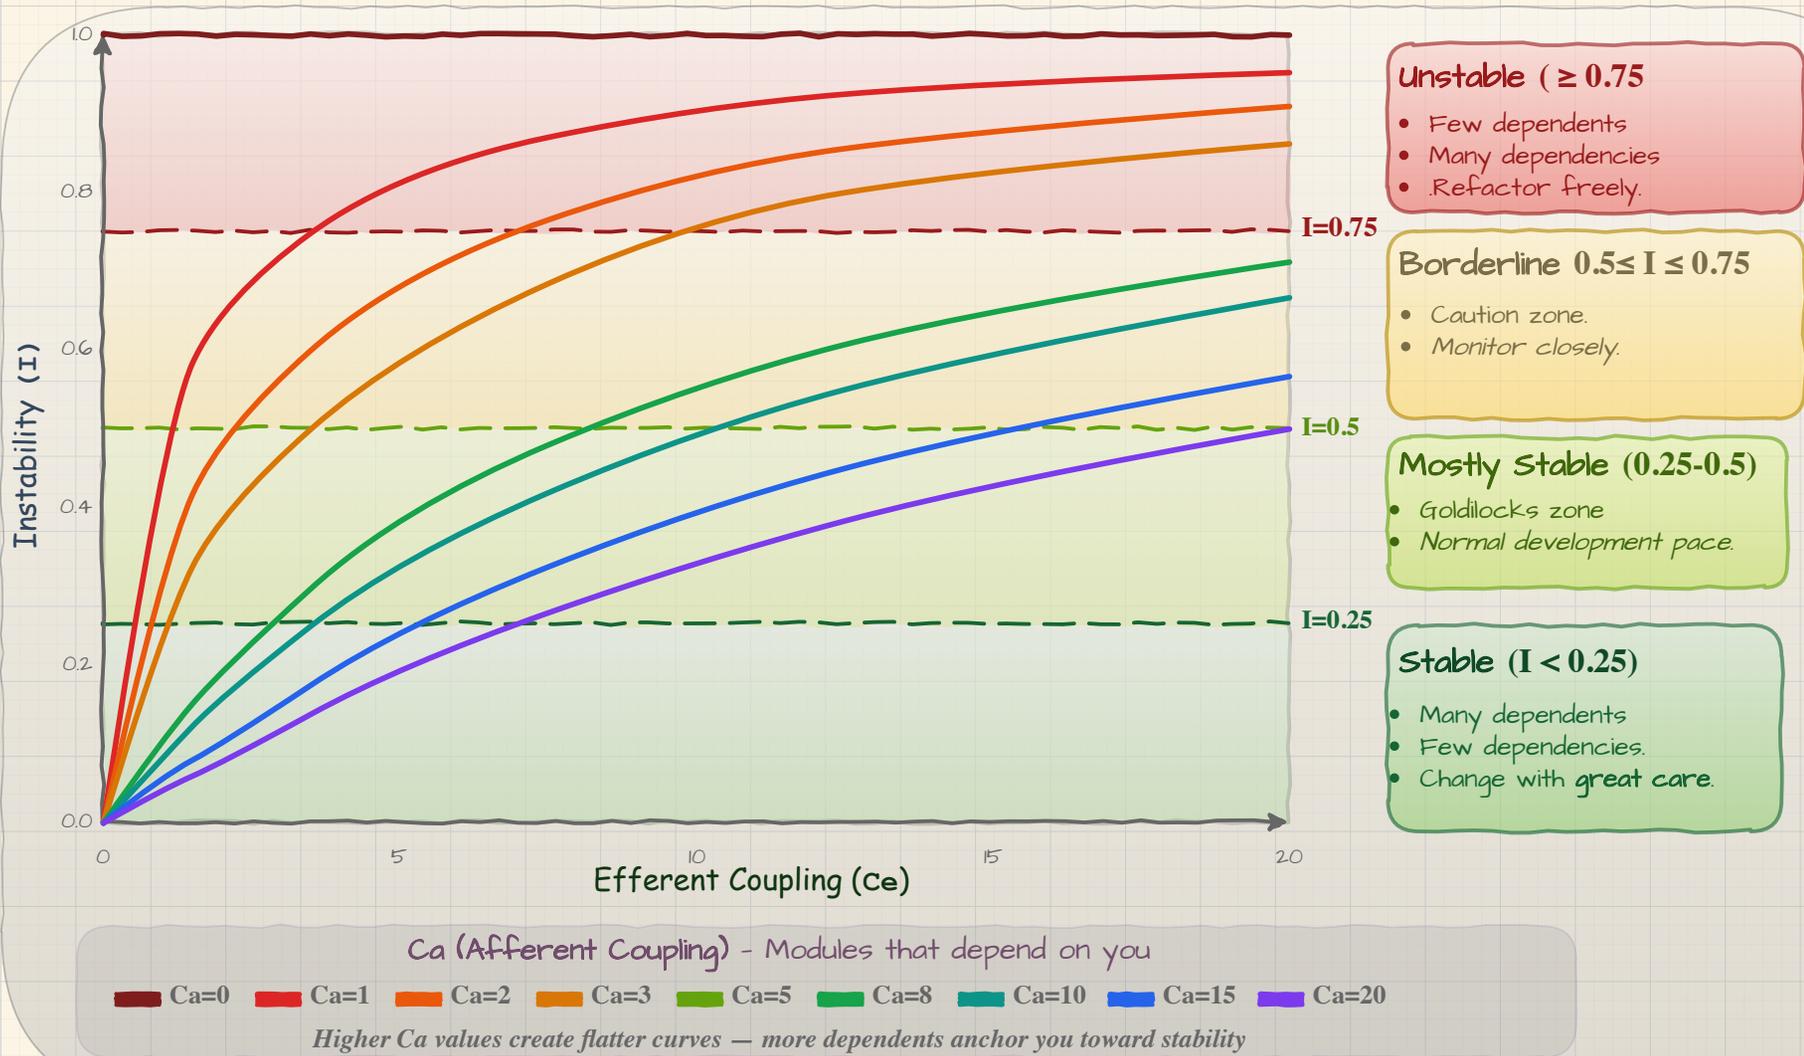

Figure 2: How Instability (I) varies with Coupling

$$I = Ce / (Ce + Ca)$$
